Content

- Context & Methodology
 - Motivations & objectives
 - Methodology
- MDA (Model Driven Architecture)
 - PIM (Platform Independant Model)
 - PSM (Platform Specific Model)
- Transformations in Gaspard
 - Metamodels
 - Transformation Engin : ModTransf
 - Rules
- An Example
- Conclusion

Motivations & Objectives

- Two particularities of Embedded Systems.
 - Dedicated to specific tasks.
 - Availability of a wide range of processors and processor architectures.
- Reduce Cost & Time to market.
- How can MDA help in designing Embedded Systems ?

MDA Transformations

MDA Major Steps

MDA Basic Framework

MDA Transformations In Gaspard Project

Metamodels

- Definition of a metamodel for:
 - Application
 - Architecture
 - Association
 - TLM Metamodel
(see Arnaud's presentation)

Transformation Engine : modTransf (1/2)

- Based on the QVT proposals
- Features
 - Multi models as inputs and outputs
 - Different kind of models: MOF and JMI, XML with schema, graph of objects
 - Can be Customized
- Available for free download at:
www.lifl.fr/~dumoulin/mdaTransf/

Transformation Engine : modTransf (2/2)

Transformation rules

- XML based
- Express how input metamodel concepts are transformed into output metamodel concepts
- Structure of a rule
 - Guard : condition under which the rule is applied
 - Action : describes the transformation

XML Rule : An example

```

<rule ruleName="etComponent">
  <description> Transform an etComponent</description>
  <leftConditions>
    <concept type="Class" stereotype="elementaryComponent" model="tau" use="required"/> guard
  </leftConditions>
  <rightConditions>
    <concept type="Signal_Processing ElementaryComponent" model="isp"/> Create action
  </rightConditions>
  <actions>
    <copyPrimitive actionName="name" leftProperty="name" rightProperty="name"/>
    <copyPrimitive actionName="code">
      <left>
        <taggedValue stereotype="elementaryComponent" name="code"/> src
      </left>
      <right>
        <property name="code"/> target
      </right>
    </copyPrimitive>
    <transform actionName="attribute" leftProperty="OwnedMember.attribute" rightProperty="feature"/>
    <transform actionName="port" leftProperty="OwnedMember.port" rightProperty="port" use="optional"/>
    <transform actionName="connector" leftProperty="OwnedMember.connector" rightProperty="connector" use="optional"/>
  </actions>
</rule>

```

Example

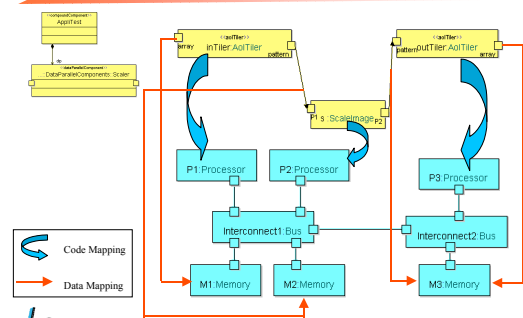

Application model

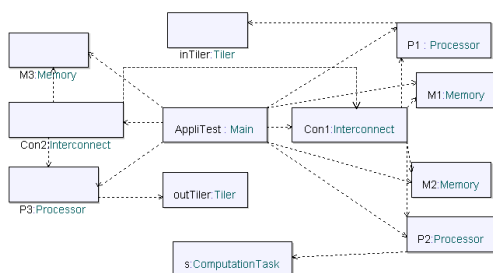

Architecture model

Association

Output SystemC TLM model

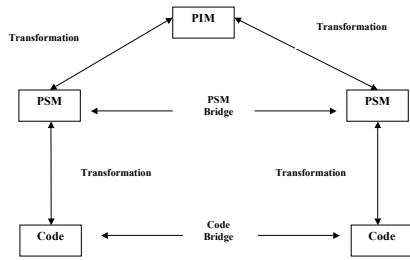

What have we gained from the MDA

- Transformations are expressed at the metamodels level
 - Use of the same transformation rules as long as the metamodels remain unchanged
 - Ease of testing different combinations of hardware software
- Multi-platforms
- Inter-operability

Interoperability

Conclusion

- Our proposal
 - Design the metamodels (domain specific) : both input and output
 - Create the models (instances of metamodels) to transform.
 - Write the rules for transformation
 - Transform with ModTransf

Thank you for your
attention
